#### Abstract

In classical logic, existential and universal quantifiers express that there exists at least one individual satisfying a formula, or that all individuals satisfy a formula. In many logics, these quantifiers have been generalized to express that, for a non-negative integer $n$, at least $n$ individuals or all but $n$ individuals satisfy a formula. In modal logics, graded modalities generalize standard existential and universal modalities in that they express, e.g., that there exist at least $n$ accessible worlds satisfying a certain formula. Graded modalities are useful expressive means in knowledge representation; they are present in a variety of other knowledge representation formalisms closely related to modal logic. A natural question that arises is how the generalization of the existential and universal modalities affects the decidability problem for the logic and its computational complexity, especially when the numbers in the graded modalities are coded in binary. In this paper we study the graded $\mu$-calculus, which extens graded modal logic with fixed-point operators, or, equivalently, extends classical $\mu$-calculus with graded modalities. We prove that the decidability problem for graded $\mu$-calculus is EXPTIME-complete - not harder than the decidability problem for $\mu$-calculus, even when the numbers in the graded modalities are coded in binary.

## 1 Introduction

In classical logic, existential and universal quantifi ers express that there exists at least one individual satisfying a formula, or that all individuals satisfy a formula. In many logics, these quantifi ers have been generalized to express that, for a non-negative integer $n$, at least $n$ individuals or all but $n$ individuals satisfy a formula. For example, predicate logic has been extended with so-called counting quantifiers $\exists \geq n$ and $\exists \leq n$ [GOR97,GMV99,PST00]. In modal logics, graded modalities [Fin72,vdHD95,Tob01] generalize standard existential and universal modalities in that they express, e.g., that there exist at least $n$ accessible worlds satisfying a certain formula. In description logics, number restrictions have always played a central role; e.g., they are present in almost all knowledge-representation systems based on description logic [PSMB ${ }^{+} 91, \mathrm{BFH}^{+} 94$, Hor98,HM01]. Indeed, in a typical such system, one can describe cars as those vehicles having at least four wheels, and bicyles as those vehicles having exactly two wheels.

A natural question that arises is how the generalization of the existential and universal quantifi ers affects the decidability problem for the logic and its computational complexity. The complexity of a variety of description logics with different forms of number restrictions has been investigated; see, e.g. [DLNdN91,HB91,DL94b,BBH96,BS99,Tob00]. It turned
out that, in many cases, one can extend a logic with these forms of counting quantifi ers without increasing its computational complexity. On the other hand, in some cases the extension makes the logic much more complex. A prominent example is the guarded fragment of first order logic, which becomes undecidable when extended with a very weak form of counting quantifi ers (global functionality conditions on binary relations) [Grä99].

When investigating the complexity of a logic with a form of counting quantifi ers, one must decide how the numbers in these quantifi ers contribute to the length of a formula, i.e., to the input of a decision procedure. Assuming that these numbers are coded in unary (i.e., $|\exists \geq n x . \varphi(x)|=n+|\varphi(x)|$ ) might seem odd, but is an assumption often made, for example in description and predicate logics. It reflects the way in which many decision procedures for these logic work: they explicitly generate $n$ individuals for $\exists \geq n$. In contrast, the assumption that the numbers are coded in binary (i.e., $\left|\exists \geq{ }^{n} x \cdot \varphi(x)\right|=\lceil\log n\rceil+|\varphi(x)|$ ) corresponds more closely to our intuition on the length of a formula, but it is not clear whether and how decision procedures can avoid the exponential blow up that a translation from the binary to the unary coding involves.

It is an interesting question whether the complexity of a logic is sensitive to the coding of numbers in counting quantifi ers. It seems as if many logics are insensitive to the coding, i.e., both complexities coincide, even though one has to "work harder" for binary coding. For many logics with counting quantifi ers, the complexity of the satisfi ability problem is known for unary coding only, and is unknown for binary coding. For example, $\mathbf{C}^{2}$ (twovariable first-order logic with counting) is known to be NEXPTimE-complete if numbers in counting quantifi ers are coded in unary [PST00]. While this coincides with the complexity of first-order two-variable logic without counting [GKV97], the complexity of $\mathbf{C}^{2}$ with binary coding is, to the best of our knowledge, unknown so far. Similarly, all the above mentioned complexity results for description and modal logics, with the exception of [Tob00,Tob01], assume unary coding of numbers.

In [Tob00,Tob01], Tobies studies graded modal logic, the extension of modal logic with graded modalities. He proves that the decidability problem for this logic is PSPACEcomplete — not harder than the decidability problem for classical modal logic [Lad77], even when the numbers in the graded modalities are coded in binary. The binary coding requires additional technical machinery. Indeed, one cannot simply generate (exponentially many) individuals, but use some form of book keeping to keep track and count the individuals required by counting quantifi ers.

The $\mu$-calculus [Koz83] extends modal logic with least and greatest fi xpoint operators. The extension makes $\mu$-calculus a highly expressive logic, of great theoretical and practical interest (cf. [Eme97]). In this paper, we study the graded $\mu$-calculus, i.e., $\mu$-calculus with graded modalities. We show that the decidability problem for graded $\mu$-calculus is ExpTime-complete - not harder than the decidability problem for classical $\mu$-calculus [FL79], even if the numbers are coded in binary. Our result substantiates the above hypothesis that most logics are insensitive to the coding of numbers, and is interesting for two additional reasons. Firstly, many relevant description, modal, and dynamic logics are fragments of the graded $\mu$-calculus; see, e.g., [Sch94,DL94b,DL94a]. Hence we obtain corresponding ExpTimE upper bounds for these fragments for free. Secondly, other relevant description, modal, and dynamic logics are close relatives of the graded $\mu$-calculus, and we could thus use the techniques developed here to prove EXPTIME upper bounds for these relatives using similar techniques.

Our techniques are based on the automata-theoretic approach [VW86,SE89, Var97]: to develop a decision procedure for a logic with the tree-model property, one first develops an appropriate notion of tree automata and studies their emptiness problem. The satisfi ability problem for the logic is then reduced to the automata emptiness problem. We show here that the appropriate notion of automata is that of graded alternating tree automata, which generalize standard alternating tree automata by having the ability to count the number of successors that satisfy a certain condition (standard alternating automata can only count up to one). We show that graded $\mu$-calculus has a tree model property and that, given a formula $\varphi$, we can construct a graded alternating automaton $\mathcal{A}_{\varphi}$ that accepts exactly the (tree abstractions of) models of $\varphi$. The size of $\mathcal{A}_{\varphi}$ is linear in $|\varphi|$, even if numbers in graded modalities are coded in binary. We then present an ExpTime decision procedure for the emptiness of graded alternating automaton by an appropriate translation into graded non-deterministic automata (with an exponential blow-up in the size of the automaton), and show that emptiness of graded non-deterministic automata can be decided in polynomial time. Like other automata-based decision procedures, the techniques developed here can be re-used: once a suitable class of automata for a certain class of logics is designed (together with the corresponding emptiness test), these automata can be easily re-used for similar logics. In particular, our technique can be easily extended to handle in ExpTime $\mu$-calculus with fractional modalities, where we can express, e.g., that at least half of the accessible worlds satisfy some predicate, as well as all modalities that involve polynomially-checkable conditions on the number of accessible words that satisfy a formula.

## 2 The Graded $\mu$-Calculus

The graded $\mu$-calculus is a propositional modal logic augmented with least and greatest fi xpoint operators [Koz83]. Specifi cally, we consider a $\mu$-calculus where formulas are constructed from atomic propositions with Boolean connectives, the graded modalities $\langle n, \alpha\rangle$ ("exist at least $n \alpha$-successors") and $[n, \alpha]$ ("all but at most $n \alpha$-successors"), as well as least $(\mu)$ and greatest $(\nu)$ fi xpoint operators. We assume that $\mu$-calculus formulas are written in positive normal form (negation is applied only to atomic propositions). Formally, given a set AP of atomic propositions, a set Var of propositional variables, and a set Prog of (atomic) programs, the set of formulas of the graded $\mu$-calculus is the smallest set such that the following holds.

- true, false, $p$ and $\neg p$, for $p \in \mathrm{AP}$, are formulas,
- $x \in \mathrm{Var}$ is a formula, and
- if $\varphi_{1}$ and $\varphi_{2}$ are formulas, $\alpha$ is a program, $n$ is a non-negative integer, and $x$ is a propositional variable, then $\varphi_{1} \wedge \varphi_{2}, \varphi_{1} \vee \varphi_{2},\langle n, \alpha\rangle \varphi_{1},[n, \alpha] \varphi_{1}, \mu y \cdot \varphi_{1}(y)$, and $\nu y . \varphi_{1}(y)$ are formulas.

A propositional variable $x$ occurs free in a formula if it is not in the scope of a fixpoint operator. Note that $x$ may occur both bound and free in a formula. A sentence is formula that contains no free variables. We use $\lambda$ to denote a fi xpoint operator $\mu$ or $\nu$. For a $\lambda$ formula $\lambda x . \varphi(x)$, we write $\varphi(\lambda x . \varphi(x))$ to denote the formula that is obtained by replacing each free occurrence of $x$ in $\varphi$ with $\lambda x . \varphi(x)$. We refer to formulas of the form $\langle n, \alpha\rangle \varphi_{1}$ and $[n, \alpha] \varphi_{1}$ as atleast and allbut formulas, respectively.

We say that a formula $\varphi$ counts up to $b$ if the maximal integer occurring in graded modalities in $\varphi$ is $b-1$. We refer to $b$ as the counting bound of $\varphi$. We assume that the
integers in graded modalities are given in binary. The length of $\varphi$, denoted $|\varphi|$, reflects this fact. Formally, $|\varphi|$ is defi ned by induction on the structure of $\varphi$ in a standard way, with $\left|\langle n, \alpha\rangle \varphi_{1}\right|=\lceil\log n\rceil+1+\left|\varphi_{1}\right|$, and similarly for $\left|[n, \alpha] \varphi_{1}\right|$.

We defi ne the semantics of graded $\mu$-calculus with respect to a Kripke structure $K=$ $\langle\mathrm{AP}, \operatorname{Prog}, W, R, L\rangle$, where AP is the set of atomic propositions, Prog is the set of programs, $W$ is a set of points, $R:$ Prog $\longrightarrow 2^{W \times W}$ assigns to each program a binary relation on $W$, and $L:$ AP $\longrightarrow 2^{W}$ assigns to each atomic proposition the set of points in which it holds. For a point $w$ and a program $\alpha$, let $\operatorname{succ}_{R}(w, \alpha)=\{u:(w, u) \in R(\alpha)\}$ denote the successors of $w$ in the program $\alpha$. Given a Kripke structure $K=\langle\mathrm{AP}, \operatorname{Prog}, W, R, L\rangle$ and variables $x_{1}, \ldots, x_{m}$, a valuation $\mathcal{V}:\left\{x_{1}, \ldots, x_{m}\right\} \longrightarrow 2^{W}$ maps each variable to a subset of $W$. For a valuation $\mathcal{V}$, a variable $x$, and a set of points $W^{\prime} \subseteq W$, let $\mathcal{V}\left[x / W^{\prime}\right]$ denote the valuation that is obtained from $\mathcal{V}$ by assigning $W^{\prime}$ to $x$.

A formula $\varphi$ is interpreted over a Kripke structure $K=\langle\mathrm{AP}, \operatorname{Prog}, W, R, L\rangle$ as a mapping $\varphi^{K}$ that associates, with each valuation $\mathcal{V}$, a subset $\varphi^{K}(\mathcal{V})$ of $W$. This mapping is defi ned inductively as follows.

$$
\begin{aligned}
& \text { true }{ }^{K}(\mathcal{V})=W, \text { false }^{K}(\mathcal{V})=\emptyset, \\
& \text { for } p \in \mathrm{AP} \text {, we have } p^{K}(\mathcal{V})=L(p) \text { and }(\neg p)^{K}(\mathcal{V})=W \backslash L(p), \\
& \left(\varphi_{1} \wedge \varphi_{2}\right)^{K}(\mathcal{V})=\left(\varphi_{1}\right)^{K}(\mathcal{V}) \cap\left(\varphi_{2}\right)^{K}(\mathcal{V}), \\
& \left(\varphi_{1} \vee \varphi_{2}\right)^{K}(\mathcal{V})=\left(\varphi_{1}\right)^{K}(\mathcal{V}) \cup\left(\varphi_{2}\right)^{K}(\mathcal{V}), \\
& (\langle n, \alpha\rangle \varphi)^{K}(\mathcal{V})=\left\{u \in W: \mid\left\{v \mid(u, v) \in R(\alpha) \text {, and } v \in \varphi^{K}(\mathcal{V})\right\} \mid>n\right\} \\
& ([n, \alpha] \varphi)^{K}(\mathcal{V})=\left\{u \in W: \mid\left\{v \mid(u, v) \in R(\alpha), \text { and } v \notin \varphi^{K}(\mathcal{V})\right\} \mid \leq n\right\} \\
& (\mu y . \varphi(y))^{K}(\mathcal{V})=\bigcap\left\{W^{\prime} \subseteq W \mid \varphi^{K}\left(\mathcal{V}\left[x / W^{\prime}\right]\right) \subseteq W^{\prime}\right\} \\
& (\nu y \cdot \varphi(y))^{K}(\mathcal{V})=\bigcup\left\{W^{\prime} \subseteq W \mid \varphi^{K}\left(\mathcal{V}\left[x / W^{\prime}\right]\right) \supseteq W^{\prime}\right\}
\end{aligned}
$$

Intuitively, a state $w$ of $K$ satisfi es the atleast formula $\langle n, \alpha\rangle \varphi$ iff at least $n+1$ successors of $w$ in $\alpha$ satisfy $\varphi$. Dually, $w$ satisfi es the allbut formula $[n, \alpha] \varphi$ iff all but at most $n$ successors of $w$ in $\alpha$ satisfy $\varphi$. Note that $\neg\langle n, \alpha\rangle \varphi$ is equivalent to $[n, \alpha] \neg \varphi$. Indeed, $\neg\langle n, \alpha\rangle \varphi$ means that less than $n+1$ successors of $w$ satisfy $\varphi$, that is, at most $n$ successors do not satisfy $\neg \varphi$. The least and greatest fi xpoint operators are interpreted as in $\mu$-calculus; thus, for example, $\mu y \cdot p \vee\langle 1, \alpha\rangle y$ is satisfi ed in a point $w$ if either $w$ satisfi es $p$ or $w$ has two different $\alpha$-successors each of which either satisfi es $p$ or has two different $\alpha$-successors etc., or equivalently, $w$ is a root of a binary tree embedded in the transition relation of $\alpha$ in which each path eventually reaches a point that satisfi es $p$. Note that the interpretation of a sentence is independent of valuations. For a sentence $\psi$, a Kripke structure $K=\langle\mathrm{AP}, \operatorname{Prog}, W, R, L\rangle$, and $u \in W$, we write $K, w \vDash \psi$ iff $w \in \psi^{K}$, and call $K$ a model of $\psi$. A sentence that has a model is called satisfiable.

The modalities $\langle n, \alpha\rangle \varphi$ and $[n, \alpha] \varphi$ are natural generalizations of the standard existential and universal next modalities. In particular, $\langle\alpha\rangle \varphi$ and $[\alpha] \varphi$ of modal logic are equivalent to $\langle 0, \alpha\rangle \varphi$ and $[0, \alpha] \varphi$, respectively, and the number restrictions $(\geq n r \varphi)$ and $(\leq n r \varphi)$ for a role $r$ in description logics [HB91] are equivalent to $\langle n-1, r\rangle \varphi$ and $[n, r] \neg \varphi$, respectively (note that ( $\geq 0 r \varphi)$ is equivalent to true).

For technical convenience, we also restrict our attention to formulas and Kripke structures in which only one program occurs. For the standard $\mu$-calculus, the reduction to a single program uses, for each atomic program $\alpha$, a new atomic proposition $p_{\alpha}$ and translates $\langle\alpha\rangle \varphi$ to $\diamond\left(\varphi \wedge p_{\alpha}\right)$, and $[\alpha] \varphi$ to $\square\left(\varphi \vee \neg p_{\alpha}\right)$. In the presence of graded modalities, we can proceed analogously, translating $\langle n, \alpha\rangle \varphi$ to $\langle n\rangle\left(\varphi \wedge p_{\alpha}\right)$, and $[n, \alpha] \varphi$ to $[n]\left(\varphi \vee \neg p_{\alpha}\right)$, where the graded modalities $\langle n\rangle$ and $[n]$ are evaluated with respect to a single accessibil-
ity relation $R$. We will accordingly refer to Kripke structures $K=\langle\mathrm{AP}, W, R, L\rangle$ with $R \subseteq W \times W$, and use $\operatorname{succ}_{R}(w)$ to denote the successors of $w$.

Note that we can also add new atomic propositions that would take care of the counting done in graded modalities. Formally, if $\varphi$ counts up to $b$, we add propositions $c_{1}, \ldots, c_{b}$, conjoin $\varphi$ with a requirement that exactly one $c_{i}$ holds in each point, that successors that are labeled by the same $c_{i}$ agree on their label with respect to all formulae in the closure of $\varphi$, and replace an atleast modality $\langle n, \psi\rangle$ by a $\bigvee_{\left\{j_{1}, \ldots, j_{n+1}\right\} \subseteq\{1, \ldots, b\}} \bigwedge_{1 \leq i \leq n+1} \diamond\left(\psi \wedge c_{j_{i}}\right)$, and dually for allbut modalities. The $\mu$-calculus formula we get is satisfi able iff $\varphi$ is satisfi able, yet the length of each disjunct that replaces a graded modality is exponential in $b$. Since the bounds in the graded modalities are written in binary, the length of the formula we get is doubly exponential in the length of $\varphi$.

A tree is a set $T \subseteq \mathbb{N}^{*}$ such that if $x \cdot c \in T$ where $x \in \mathbb{N}^{*}$ and $c \in \mathbb{N}$, then also $x \in T$. The elements of $T$ are called nodes, and the empty word $\varepsilon$ is the root of $T$. For every $x \in T$, the nodes $x \cdot c$ where $c \in \mathbb{N}$ are the children of $x$. The number of children of $x$ is called the degree of $x$, and is denoted $\operatorname{deg}(x)$. The degree of a tree is the maximum degree of a node in the tree. A node is a leaf if it has no children. A path $\pi$ of a tree $T$ is a set $\pi \subseteq T$ such that $\varepsilon \in \pi$ and for every $x \in \pi$, either $x$ is a leaf or there exists a unique $c \in \mathbb{N}$ such that $x \cdot c \in \pi$. Given an alphabet $\Sigma$, a $\Sigma$-labeled tree is a pair $\langle T, V\rangle$ where $T$ is a tree and $V: T \rightarrow \Sigma$ maps each node of $T$ to a letter in $\Sigma$. Note that an infi nite word in $\Sigma^{\omega}$ can be viewed as a $\Sigma$-labeled tree in which the degree of all nodes is 1 .

In Appendix A, we show that the graded $\mu$-calculus has the tree model property. Thus, if a formula $\varphi$ is satisfi able, it is also satisfi able in a tree. Moreover, the number of atleast formulas in $\varphi$ and its counting bound induce a suffi cient degree for the tree. Formally, we have the following.

Theorem 1. Consider a sentence $\psi$ such that $\psi$ has $l$ atleast subsentences, each counting to at most $b$. If $\psi$ is satisfiable, then $\psi$ is satisfied in a tree whose degree is at most $l \cdot(b+1)$.

## 3 Graded Automata

Automata over infinite trees (tree automata) run over $\Sigma$-labeled trees that have no leaves [Tho90]. Alternating automata generalize nondeterministic tree automata and were first introduced in [MS87]. For simplicity, we refer fi rst to automata over binary trees (i.e., when $T=\{0,1\}^{*}$ ). Consider a nondeterministic tree automaton $\mathcal{A}=\left\langle\Sigma, Q, \delta, q_{0}, \alpha\right\rangle$, where $\Sigma$ is the input alphabet, $Q$ is a fi nite set of states, $\delta$ is a transition function,, $\mathcal{Q} \in Q$ is an initial state, and $\alpha$ specifi es the acceptance condition (a condition that defi nes a subset of $\mathcal{Q}$; we defi ne the parity acceptance condition below). The transition function $\delta: Q \times \Sigma \rightarrow 2^{Q^{2}}$ maps an automaton state $q \in Q$ and an input letter $\sigma \in \Sigma$ to a set of pairs of states. Each pair suggests a nondeterministic choice for the automaton's next confi guration. When the automaton is in a state $q$ as it reads a node $x$ labeled by a letter $\sigma$, it proceeds by first choosing a pair $\left\langle q_{1}, q_{2}\right\rangle \in \delta(q, \sigma)$, and then splitting into two copies. One copy enters the state $q_{1}$ and proceeds to the node $x \cdot 0$ (the left child of $x$ ), and the other copy enters the state $q_{2}$ and proceeds to the node $x \cdot 1$ (the right child of $x$ ).

For a given set $Y$, let $\mathcal{B}^{+}(Y)$ be the set of positive Boolean formulas over $Y$ (i.e., Boolean formulas built from elements in $Y$ using $\wedge$ and $\vee$ ), where we also allow the formulas true and false and, as usual, $\wedge$ has precedence over $\vee$. For a set $X \subseteq Y$ and a formula $\theta \in \mathcal{B}^{+}(Y)$, we say that $X$ satisfies $\theta$ iff assigning true to elements in $X$ and assigning false to elements in $Y \backslash X$ makes $\theta$ true.

We can represent the transition relation $\delta$ of a nondeterministic automaton on binary trees using $\mathcal{B}^{+}(\{0,1\} \times Q)$. For example, $\delta(q, \sigma)=\left\{\left\langle q_{1}, q_{2}\right\rangle,\left\langle q_{3}, q_{1}\right\rangle\right\}$ can be written as $\delta(q, \sigma)=\left(0, q_{1}\right) \wedge\left(1, q_{2}\right) \vee\left(0, q_{3}\right) \wedge\left(1, q_{1}\right)$, meaning that the automaton can choose between two possibilities. In the first, the copy that proceeds to direction 0 enters the state $q_{1}$ and the one that proceeds to direction 1 enters the state $q_{2}$. In the second, the copy that proceeds to direction 0 enters the state $q_{3}$ and the one that proceeds to direction 1 enters the state $q_{1}$.

In nondeterministic tree automata, each conjunction in $\delta$ has exactly one element associated with each direction. In alternating automata over binary trees, $\delta(q, \sigma)$ can be an arbitrary formula from $\mathcal{B}^{+}(\{0,1\} \times Q)$. We can have, for instance, a transition $\delta(q, \sigma)=$ $\left(0, q_{1}\right) \wedge\left(0, q_{2}\right) \vee\left(0, q_{2}\right) \wedge\left(1, q_{2}\right) \wedge\left(1, q_{3}\right)$. The above transition illustrates that several copies may go to the same direction and that the automaton is not required to send copies to all the directions.

### 3.1 Graded Alternating Parity Tree Automata

For $b \geq 0$, let $\langle[b]\rangle=\{\langle 0\rangle,\langle 1\rangle, \ldots,\langle b\rangle\}$ and $[[b]]=\{[0],[1], \ldots,[b]\}$, and let $D_{b}=$ $\{\varepsilon\} \cup\langle[b]\rangle \cup[[b]]$. A graded alternating automaton is an automaton in which the transition function $\delta$ maps a state $q$ and a letter $\sigma$ to a formula in $\mathcal{B}^{+}\left(D_{b} \times Q\right)$. Intuitively, an atom $(\varepsilon, q)$ means that the automaton sends a copy of itself in state $q$ to the current node, an atom $(\langle n\rangle, q)$ means that the automaton sends copies in states $q$ to $n+1$ different children of the current node, and $([n], q)$ means that the automaton sends copies in state $q$ to all but $n$ children of the current node. When, for instance, the automaton is in state $q$, reads a node $x$ and $\delta(q, V(x))=\left(\langle 3\rangle, q_{1}\right) \wedge\left(\varepsilon, q_{2}\right) \vee\left([2], q_{3}\right)$, it can either send four copies in state $q_{1}$ to four different children of $x$ and send a copy in state $q_{2}$ to $x$, or send copies in state $q_{3}$ to $\operatorname{deg}(x)-2$ children of $x$. So, while nondeterministic tree automata send exactly one copy to each child, graded automata can send several copies to the same child, they have $\varepsilon$ transitions, and extend symmetric automata [JW95,Wil99] by specifying the number of children that need to satisfy an existential requirement or are exempt from satisfying a universal one.

Formally, a graded automaton is a tuple $\mathcal{A}=\left\langle\Sigma, b, Q, \delta, q_{0}, \alpha\right\rangle$, where $\Sigma, Q, q_{0}$, and $\alpha$ are as in alternating automata, $b$ is a counting bound, and $\delta: Q \times \Sigma \rightarrow \mathcal{B}^{+}\left(D_{b} \times Q\right)$ is a transition function. A run of $\mathcal{A}$ on an input $\Sigma$-labeled tree $\langle T, V\rangle$ is a tree $\left\langle T_{r}, r\right\rangle$ (to be formally defi ned shortly) in which each node corresponds to a node of $T$ and is labeled by an element of $\mathbb{N}^{*} \times Q$. A node in $T_{r}$, labeled by $(x, q)$, describes a copy of the automaton that reads the node $x$ of $T$ and visits the state $q$. Note that many nodes of $T_{r}$ can correspond to the same node of $T$; in contrast, in a run of a nondeterministic automaton on $\langle T, V\rangle$ there is a one-to-one correspondence between the nodes of the run and the nodes of the tree. The labels of a node and its children have to satisfy the transition function. Formally, the run $\left\langle T_{r}, r\right\rangle$ is an $\left(\mathbb{N}^{*} \times Q\right)$-labeled $\mathbb{N}$-tree such that $\varepsilon \in T_{r}$ and $r(\varepsilon)=\left(\varepsilon, q_{0}\right)$, and for all $y \in T_{r}$ with $r(y)=(x, q)$ and $\delta(q, V(x))=\theta$, there is a (possibly empty) set $S \subseteq D_{b} \times Q$, such that $S$ satisfi es $\theta$, and for all $(c, s) \in S$, the following holds:

- If $c=\varepsilon$, then there is $j \in \mathbb{N}$ such that $y \cdot j \in T_{r}$ and $r(y \cdot j)=(x, s)$.
- If $c=\langle n\rangle$, then there are distinct $i_{1}, \ldots, i_{n+1} \in \mathbb{N}$ such that for all $1 \leq j \leq n+1$, there is $j^{\prime} \in \mathbb{N}$ such that $y \cdot j^{\prime} \in T_{r}$ and $r\left(y \cdot j^{\prime}\right)=\left(x \cdot i_{j}, s\right)$.
- If $c=[n]$, then there are distinct $i_{1}, \ldots, i_{\operatorname{deg}(x)-n} \in \mathbb{N}$ such that for all $1 \leq j \leq$ $\operatorname{deg}(x)-n$, there is $j^{\prime} \in \mathbb{N}$ such that $y \cdot j^{\prime} \in T_{r}$ and $r\left(y \cdot j^{\prime}\right)=\left(x \cdot i_{j}, s\right)$.

Note that if $\theta=$ true, then $y$ need not have children. This is the reason why $T_{r}$ may have leaves. Also, since there exists no set $S$ as required for $\theta=$ false, we cannot have a run that takes a transition with $\theta=$ false.

A run $\left\langle T_{r}, r\right\rangle$ is accepting if all its infi nite paths satisfy the acceptance condition. We consider here the parity acceptance condition, where $\alpha=\left\{F_{1}, F_{2}, \ldots, F_{k}\right\}$ is such that $F_{1} \subseteq F_{2} \subseteq \cdots \subseteq F_{k}=Q$. The number $k$ of sets in $\alpha$ is called the index of the automaton. Given a run $\left\langle T_{r}, r\right\rangle$ and an infi nite path $\pi \subseteq T_{r}$, let $\inf (\pi) \subseteq Q$ be such that $q \in \inf (\pi)$ if and only if there are infi nitely many $y \in \pi$ for which $r(y) \in \mathbb{N}^{*} \times\{q\}$. That is, $\inf (\pi)$ contains exactly all the states that appear infi nitely often in $\pi$. A path $\pi$ satisfi es a parity acceptance condition $\alpha=\left\{F_{1}, F_{2}, \ldots, F_{k}\right\}$ iff the minimal index $i$ for which $\inf (\pi) \cap$ $F_{i} \neq \emptyset$ is even. An automaton accepts a tree if and only if there exists a run that accepts it. We denote by $\mathcal{L}(\mathcal{A})$ the set of all $\Sigma$-labeled trees that $\mathcal{A}$ accepts.

Theorem 2. Given a sentence $\psi$ of the graded $\mu$-calculus ${ }^{1}$ that counts up to $b$, we can construct a graded alternating parity automaton $\mathcal{A}_{\psi}$ such that

1. $\mathcal{A}_{\psi}$ accepts exactly all trees that satisfy $\psi$.
2. $\mathcal{A}_{\psi}$ has $|\psi|$ states, index $|\psi|$, and counting bound $b$.

Proof. The construction generalizes the one for $\mu$-calculus sentences and parity automata [KVW00]. Given $\psi$, we defi ne the graded alternating automaton $\mathcal{A}_{\psi}=\left\langle 2^{\mathrm{AP}}, b, \mathrm{cl}(\psi), \delta, \psi, \alpha\right\rangle$, as follows:
For all $\sigma \in 2^{\mathrm{AP}}$, we defi ne:

$$
\begin{aligned}
\delta(p, \sigma) & =\text { true if } p \in \sigma, & \delta(p, \sigma) & =\text { false if } p \notin \sigma, \\
\delta(\neg p, \sigma) & =\text { true if } p \notin \sigma, & \delta(\neg p, \sigma) & =\text { false if } p \in \sigma, \\
\delta\left(\varphi_{1} \wedge \varphi_{2}, \sigma\right) & =\left(\varepsilon, \varphi_{1}\right) \wedge\left(\varepsilon, \varphi_{2}\right), & \delta\left(\varphi_{1} \vee \varphi_{2}, \sigma\right) & =\left(\varepsilon, \varphi_{1}\right) \vee\left(\varepsilon, \varphi_{2}\right), \\
\delta(\langle n\rangle \varphi, \sigma) & =(\langle n\rangle, \varphi), & \delta([n] \varphi, \sigma) & =([n], \varphi), \\
\delta(\mu y . f(y), \sigma) & =\delta(f(\mu y \cdot f(y)), \sigma), & \delta(\nu y \cdot f(y), \sigma) & =\delta(f(\nu y \cdot f(y)), \sigma)) .
\end{aligned}
$$

For a $\mu$-calculus sentence $\psi$ and a subformula $\varphi=\lambda y . f(y)$ of $\psi$, we defi ne the alternation level of $\varphi$ in $\psi$, denoted $a l_{\psi}(\varphi)$, as follows [BC96].

- If $\varphi$ is a sentence, then $a l_{\psi}(\varphi)=1$.
- Otherwise, let $\xi=\lambda^{\prime} x . g(x)$ be the innermost $\mu$ or $\nu$ subformula of $\psi$ that has $\varphi$ as a strict subformula. Then, if $x$ is free in $\varphi$ and $\lambda^{\prime} \neq \lambda$, we have $a l_{\psi}(\varphi)=a l_{\psi}(\xi)+1$. Otherwise, we have $a l_{\psi}(\varphi)=a l_{\psi}(\xi)$.

Intuitively, the alternation level of $\varphi$ in $\psi$ is the number of alternating fi xpoint operators we have to "wrap $\varphi$ with" in order to reach a sub-sentence of $\psi$.

Let $d$ be the maximal alternation level of subformulas of $\psi$. Denote by $G_{i}$ the set of all the $\nu$-formulas in $\mathrm{cl}(\psi)$ of alternation level $i$. Denote by $B_{i}$ the set of all $\mu$-formulas in $\mathrm{cl}(\psi)$ of alternation depth less than or equal to $i$. Now, $\alpha=\left\{F_{0}, \ldots, F_{2 d}\right\}$, where $F_{0}=\emptyset$

[^0]and, for every $1 \leq i \leq d$, we have $F_{2 i-1}=F_{2 i-2} \cup B_{i}$ and $F_{2 i}=F_{2 i-1} \cup G_{i}$. It is easy to see that $F_{1} \subseteq F_{2} \subseteq \cdots \subseteq F_{2 d}$.

### 3.2 Graded Nondeterministic Parity Tree Automata

For an integer $b$, a $b$-bound is pair in $B_{b}=\{(>, 0),(\leq, 0),(>, 1),(\leq, 1), \ldots,(>, b),(\leq$ $, b)\}$. For a set $X$, a subset $P \subseteq X$, and a tuple $t=\left\langle x_{1}, \ldots, x_{m}\right\rangle \in X^{m}$, for some $m>0$, the weight of $P$ in $t$, denoted weight $(P, t)$, is the number of elements in $t$ that are members of $P$. That is, weight $(P, t)=\left|\left\{i: x_{i} \in P\right\}\right|$. For example, weight $(\{1,2,3\},\langle 1,2,2,4,2\rangle)=$ 4. We say that $t$ satisfi es a $b$-bound $(>, n)$ with respect to $P$ if $w e i g h t(P, t)>n$, and $t$ satisfi es a $b$-bound $(\leq, n)$ with respect to $P$ if $w \operatorname{eight}(P, t) \leq n$.

For a set $Y$, we use $\mathcal{B}(Y)$ to denote the set of all Boolean formulas over atoms in $Y$. Each formula $\theta \in \mathcal{B}(Y)$ induces a set $\operatorname{sat}(\theta) \subseteq 2^{Y}$ such that $x \in \operatorname{sat}(\theta)$ iff $x$ satisfi es $\theta$. For an integer $b \geq 0$, a b-counting constraint for $2^{Y}$ is a relation $C \subseteq \mathcal{B}(Y) \times B_{b}$. For example, if $Y=\left\{y_{1}, y_{2}, y_{3}\right\}$, then we can have

$$
C=\left\{\left\langle y_{1} \vee \neg y_{2},(\leq, 3)\right\rangle,\left\langle y_{3},(\leq, 2)\right\rangle,\left\langle y_{1} \wedge y_{3},(>, 1)\right\rangle\right\}
$$

A tuple $t=\left\langle x_{1}, \ldots, x_{m}\right\rangle \in\left(2^{Y}\right)^{m}$ satisfi es the $b$-counting constraint $C$ if for all $\langle\theta, \xi\rangle \in$ $C$, the tuple $t$ satisfi es $\xi$ with respect to $\operatorname{sat}(\theta)$. Thus, when $\theta \in \mathcal{B}(Y)$ is paired with $(>, n)$, at least $n+1$ elements of $t$ should satisfy $\theta$, and when $\theta$ is paired with $(\leq, n)$, at most $n$ elements in the tuple satisfy $\theta$. For example, the tuple $t_{1}=\left\langle\emptyset,\left\{y_{1}\right\},\left\{y_{2}\right\},\left\{y_{1}, y_{3}\right\}\right\rangle$ does not satisfy the constraint $C$ above, as the number of sets in $t_{1}$ that satisfy $y_{1} \wedge y_{3}$ is one. On the other hand, the tuple $t_{2}=\left\langle\emptyset,\left\{y_{2}\right\},\left\{y_{1}, y_{2}, y_{3}\right\},\left\{y_{1}, y_{3}\right\}\right\rangle$ satisfi es $C$. Indeed, three sets in $t_{2}$ satisfy $y_{1} \vee \neg y_{2}$, two sets satisfy $y_{3}$, and two sets satisfy $y_{1} \wedge y_{3}$.

For a constraint $C$, the width of $C$ is the number of $\theta \in \mathcal{B}(Y)$ for which there is a $b$-bound $\xi$ such that $\langle\theta, \xi\rangle \in C$. Note that $\theta$ may be paired with several $b$-bounds. Still, it is easy to replace $C$ by an equivalent constraint $C^{\prime}$ (that is, a tuple $t$ satisfi es $C$ iff $t$ satisfi es $C$ ) in which $\theta$ is paired with at most one constraint of the form $(>, n)$ and at most one constraint of the form $(\leq, n)$. We assume that we work with such minimized constraints. Accordingly, for two $b$-counting constraints $C_{1}$ and $C_{2}$, we denote by $C_{1} \oplus C_{2}$ the minimization of $C_{1} \cup C_{2}$. That is, if $\left\langle\theta,\left(>, n_{1}\right)\right\rangle \in C_{1}$ and $\left\langle\theta,\left(>, n_{2}\right)\right\rangle \in C_{2}$, then $C_{1} \oplus C_{2}$ contains only $\left\langle\theta,\left(>, \max \left\{n_{1}, n_{2}\right\}\right)\right\rangle$, and dually for constraints of the form ( $\leq$ $, n)^{2}$.

We say that a constraint $C$ is short if all the formulas $\theta$ that appear in $C$ are of size linear in $|Y|$ and the width of $C$ is at most $|Y|$. We use $\mathcal{C}(Y, b)$ to denote the set of all short $b$-counting constraints for $2^{Y}$. We assume that the integers in the constraints are coded in binary. Thus, the size of $C \in \mathcal{C}(Y, b)$ is $O\left(|Y|^{2}\lceil\log b\rceil\right)$.

Lemma 1. Given a constraint $C \in \mathcal{C}(Y, b)$ and a set $S \subseteq 2^{Y}$, deciding whether there is a tuple $t \in\left(2^{Y}\right)^{*}$ such that $t$ satisfies $C$ can be done in space $(1+\lceil\log (b+1)\rceil)|Y|$ or time $(2 b+2)^{|Y|}$.

Proof. Since the width of $C$ is at most $|Y|$, an algorithm that guesses $t$ (element by element) and updates a counter for each $\theta$ that participate in $C$ requires space for storing the guess

[^1]for the current element in $2^{Y}$, and for storing the values of the counters. The algorithm terminates with a positive decision when the values of the counters are such that all the $b$-bounds in $C$ are satisfi ed. There are at most $|Y|$ counters, each may count up to at most $b+1$. Thus, the space required is $|Y|+|Y|\lceil\log (b+1)\rceil$. In addition, since the length of each formula $\theta$ that participate in $C$ is linear in $|Y|$, its valuation with respect to each element of the tuple can be done in space $\log |Y|$ [Lyn77].

A graded nondeterministic parity tree automaton (GNPT, for short) is $\mathcal{A}=\left\langle\Sigma, b, Q, \delta, q_{0}, \alpha\right\rangle$, where $\Sigma$ and $b, q_{0}$, and $\alpha$ are as in GAPT, and the other components are as follows.

- The state space $Q$ is encoded by a fi nite set $Y$ of variables; that is, $Q \subseteq 2^{Y}$.
- The function $\delta: Q \times \Sigma \rightarrow \mathcal{C}(Y, b)$ maps a state and a letter to a $b$-counting constraint for $2^{Y}$.

Note that, like GAPT, a GNPT is symmetric, in the sense it cannot distinguish between the different children of a node.

A run of the graded nondeterministic automaton $\mathcal{A}$ on a $\Sigma$-labeled tree $\langle T, V\rangle$ is a $Q$-labeled tree $\langle T, r\rangle$ such that $r(\varepsilon)=q_{0}$ and for every $x \in T$, the tuple $\langle r(x \cdot 1), r(x$. $2), \ldots, r(x \cdot \operatorname{deg}(x))\rangle$ satisfi es $\delta(r(x), V(x))$. The run $\langle T, r\rangle$ is accepting if all its paths satisfy the parity acceptance condition.

We consider two special cases of GNPT.

- In forall automata, for each $q \in Q$ and $\sigma \in \Sigma$ there is $s \in Q$ such that $\delta(q, \sigma)=$ $\left\{\left\langle\left(\neg \theta_{s}\right),(\leq, 0)\right\rangle\right\}$, where $\theta_{s} \in \mathcal{B}(Y)$ is such that $\operatorname{sat}\left(\theta_{s}\right)=\{s\}$. Thus, a forall automaton is a notational invariant of a deterministic tree automaton, where the transition function maps $q$ and $\sigma$ to $\langle s, \ldots, s\rangle$.
- In safety automata, there is no acceptance condition, and all runs are accepting. Note that this does not mean that safety automata accept all trees, as it may be that on some trees the automaton does not have a run.

Lemma 2. Given a forall GNPT $\mathcal{A}_{1}$ with $n_{1}$ states and index $k$, and a safety GNPT $\mathcal{A}_{2}$ with $n_{2}$ states and counting bound $b$, we can define a GNPT $\mathcal{A}$ such that $\mathcal{L}(\mathcal{A})=\mathcal{L}\left(\mathcal{A}_{1}\right) \cap$ $\mathcal{L}\left(\mathcal{A}_{2}\right)$. Moreover, $\mathcal{A}$ has $n_{1} n_{2}$ states, index $k$, and counting bound $b$.

Proof. Let $\mathcal{A}_{1}=\left\langle\Sigma, 0,2^{Y_{1}}, \delta_{1}, q_{1}^{0}, \alpha_{1}\right\rangle$ and $\mathcal{A}_{2}=\left\langle\Sigma, b, 2^{Y_{2}}, \delta_{2}, q_{2}^{0}\right\rangle$. Then, $\mathcal{A}=\langle\Sigma, b$, $\left.2^{Y_{1} \cup Y_{2}}, \delta, q_{1}^{0} \cup q_{2}^{0}, \alpha\right\rangle$, where for a state $q \in 2^{Y_{1} \cup Y_{2}}$ and $\sigma \in \Sigma$, we defi ne $\delta(q, \sigma)=$ $\delta_{1}\left(q \cap Y_{1}, \sigma\right) \cup \delta_{2}\left(q \cap Y_{2}, \sigma\right)$. Finally, $\alpha=\alpha_{1} \times 2^{Y_{2}}$ is obtained from $\alpha_{1}$ by replacing each set $F_{i}$ in $\alpha_{1}$ by the set $F_{i} \times 2^{Y_{2}}$.

## 4 The Nonemptiness Problem for GAPT

In this section we solve the nonemptiness problem for GAPT and conclude that the decidability problem for graded $\mu$-calculus can be solved in EXPTIME. We fi rst translate GAPT to GNPT, and then solve the nonemptiness problem for GNPT.

### 4.1 From GAPT to GNPT

Consider a GAPT $\mathcal{A}=\left\langle\Sigma, b, Q, \delta, q_{0}, \alpha\right\rangle$. Let $D_{b}=(\{\varepsilon\} \cup\langle[b]\rangle \cup[[b]])$. Recall that the transition function $\delta: Q \times \Sigma \rightarrow \mathcal{B}^{+}\left(D_{b} \times Q\right)$ maps a state and a letter to a formula in
$\mathcal{B}^{+}\left(D_{b} \times Q\right)$. A restriction of $\delta$ is a partial function $\eta: Q \rightarrow 2^{D_{b} \times Q}$. For a letter $\sigma \in \Sigma$, we say that a restriction $\eta$ is relevant to $\sigma$ if for all $q \in Q$ for which $\delta(q, \sigma)$ is satisfi able (i.e., $\delta(q, \sigma)$ is not false), the set $\eta(q)$ satisfi es $\delta(q, \sigma)$. If $\delta(q, \sigma)$ is not satisfi able, then $\eta(q)$ is undefi ned. Intuitively, by choosing the atoms that are going to be satisfi ed, $\eta$ removes the nondeterminism in $\delta$. Let $F$ be the set of restrictions of $\delta$. A running strategy of $\mathcal{A}$ for a $\Sigma$-labeled tree $\langle T, V\rangle$ is an $F$-labeled tree $\langle T, f\rangle$. We say that $\langle T, f\rangle$ is relevant with respect to $\langle T, V\rangle$ if for all $x \in T$, the restriction $f(x)$ is relevant to $V(x)$.

Consider a restriction $\eta$ relevant to $\sigma$. For $q \in Q$, we say that a fi nite sequence $s=$ $s_{0}, s_{1}, \ldots, s_{l+1}$ is a step of $\eta$ with $q$ and $\sigma$ if $s_{0}=q$, for all $0 \leq i<l$, we have $\left(\varepsilon, s_{i+1}\right) \in$ $\eta\left(s_{i}\right)$, and $\left(\lambda, s_{l+1}\right) \in \eta\left(s_{l}\right)$, for $\lambda \in\langle b\rangle \cup[b]$. Thus, $s$ is a step of $\eta$ with $q$ and $\sigma$ if by following the restriction $\eta$ at a node $x$ labeled $\sigma$, a run that visits $q$ can continue by first taking $l$ subsequent $\varepsilon$-transitions and visiting $s_{0}, \ldots, s_{l}$, and then moving to a child of $x$ in state $s_{l+1}$. We refer to $\left(\lambda, s_{l+1}\right)$ as the last atom taken in the step. Note that $l$ may be 0 . We defi ne the value of $s$, denoted $\operatorname{val}(s)$, as the minimal $i$ such that there is $0<j \leq l+1$ with $s_{j} \in F_{i}$. Note that when $s$ contains only two states, its value is induced by $s_{1}$.

We say that a fi nite sequence $s=s_{0}, s_{1}, \ldots, s_{l}$ is an $\varepsilon$-lasso of $\eta$ with $q$ and $\sigma$ if $s_{0}=q$, for all $0 \leq i \leq l-1$, we have $\left(\varepsilon, s_{i+1}\right) \in \eta\left(s_{i}\right)$, and there is $0 \leq c \leq l$ such that $\left(\varepsilon, s_{c}\right) \in \eta\left(s_{l}\right)$ Thus, $s$ is an $\varepsilon$-lasso of $\eta$ with $q$ and $\sigma$ if by following the restriction $\eta$ at a node $x$ labeled $\sigma$, there is $0 \leq c \leq l$ such that a run that visits $q$ can eventually loop forever in $s_{c}, \ldots, s_{l}$ by taking subsequent $\varepsilon$-transitions. The value of $s$ with a loop starting at $c$, denoted $\operatorname{val}(s, c)$, is the minimal $i$ such that there is $c \leq j \leq l$ with $s_{j} \in F_{i}$. We say that $s$ is rejecting if there is $0 \leq c \leq l$ such that $\operatorname{val}(s)$ is odd.

A local promise for the automaton $\mathcal{A}$ is a function $\rho: Q \rightarrow 2^{Q}$. We extend $\rho$ to sets of states, thus for $P \subseteq Q$, we have $\rho(P)=\bigcup_{q \in P} \rho(q)$. Let $G$ be the set of all local promises. A promise of $\mathcal{A}$ for a $\Sigma$-labeled tree $\langle T, V\rangle$ is a $G$-labeled tree $\langle T, g\rangle$. Intuitively, in a run that proceeds according to the promise $\langle T, g\rangle$, if a node $y \cdot j$ has $s \in g(y \cdot j)(q)$ and the run visits its parent $y$ in state $q$ and proceeds by choosing an atom $\langle n\rangle s$ or $[n] s$, for some $0 \leq n \leq b$, then $y \cdot j$ is among the children of $y$ that inherit $s$.

Consider a $\Sigma$-labeled tree $\langle T, V\rangle$, a running strategy $\langle T, f\rangle$ relevant to $\langle T, V\rangle$, and a promise $\langle T, g\rangle$. We say that a $(T \times Q)$-labeled tree $\left\langle T_{r}, r\right\rangle$ is consistent with $f$ and $g$ if $\left\langle T_{r}, r\right\rangle$ suggests a possible run of $\mathcal{A}$ on $\langle T, V\rangle$ such that whenever the run $\left\langle T_{r}, r\right\rangle$ is in state $q$ as it reads a node $x \in T$, the restriction $f(x)(q)$ is defi ned, the run proceeds according to $f(x)(q)$, and it delivers requirements to each child $x \cdot j$ according to $g(x \cdot j)(q)$. Note that since the counting constraints in $f(x)(q)$ may not be satisfi ed, $\left\langle T_{r}, r\right\rangle$ may not be a legal run. Formally, $\left\langle T_{r}, r\right\rangle$ is consistent with $f$ and $g$ iff the following holds.

1. $\varepsilon \in T_{r}$ and $r(\varepsilon)=\left(\varepsilon, q_{0}\right)$.
2. Consider a node $y \in T_{r}$ with $r(y)=(x, q)$. Then, $f(x)(q)$ is defi ned, and for all $(c, s) \in f(x)(q)$, the following hold:

- If $c=\varepsilon$, then there is $j \in \mathbb{N}$ such that $y \cdot j \in T_{r}$ and $r(y \cdot j)=(x, s)$.
- If $c=\langle n\rangle$ or $c=[n]$, then for each $j \in \mathbb{N}$ with $s \in g(x \cdot j)(q)$, there is $j^{\prime} \in \mathbb{N}$ such that $y \cdot j^{\prime} \in T_{r}$ and $r\left(y \cdot j^{\prime}\right)=(x \cdot j, s)$.

For a node $x \in T$ and a state $q \in Q$, we say that $x$ is obliged to $q$ by $f, g$, and $V$ if $x$ is visited by $q$ in some labeled tree $\left\langle T_{r}, r\right\rangle$ consistent with $f$ and $g$. Note that while there may be several trees consistent with $f$ and $g$, they differ only in the order of children of nodes, thus if $x$ is visited by $q$ in some consistent tree, it is visited by all consistent trees.

Let $\Sigma^{\prime} \subseteq \Sigma \times F \times G$ be such that for all $\langle\sigma, \eta, \rho\rangle \in \Sigma^{\prime}$, we have that $\eta$ is relevant to $\sigma$. For an infi nite sequence $\left\langle\sigma_{0}, \eta_{0}, \rho_{0}\right\rangle,\left\langle\sigma_{1}, \eta_{1}, \rho_{1}\right\rangle, \ldots$ of triples in $\Sigma^{\prime}$ and a sequence (either fi nite or infi nite) $\mathbb{Q}, q_{1}, \ldots$ of states, we say that $q_{0}, q_{1}, \ldots$ is a trace induced by $\left\langle\sigma_{0}, \eta_{0}, \rho_{0}\right\rangle,\left\langle\sigma_{1}, \eta_{1}, \rho_{1}\right\rangle, \ldots$ if $q_{0}$ is the initial state of $\mathcal{A}$ and there is a function pos : $\mathbb{N} \rightarrow$ $\mathbb{N}$ such that $\operatorname{pos}(0)=0$ and for every $i \geq 0$, one of the following holds.

1. $\eta_{p o s(i)}\left(q_{i}\right)$ is empty, in which case $q_{i}$ is the last state in the trace,
2. there is $\left(\varepsilon, q_{i+1}\right) \in \eta_{p o s(i)}\left(q_{i}\right)$ and $\operatorname{pos}(i+1)=\operatorname{pos}(i)$, or
3. $\eta_{p o s(i)}\left(q_{i}\right)$ contains $\left(\langle n\rangle, q_{i+1}\right)$ or $\left([n], q_{i+1}\right), q_{i+1} \in \rho_{p o s(i)+1}\left(q_{i}\right)$, and $\operatorname{pos}(i+1)=$ $\operatorname{pos}(i)+1$.

Intuitively, $q_{0}, q_{1}, \ldots$ is a trace induced by $\left\langle\sigma_{0}, \eta_{0}, \rho_{0}\right\rangle,\left\langle\sigma_{1}, \eta_{1}, \rho_{1}\right\rangle, \ldots$, if for every path $\pi \subseteq T$ and for every run $\left\langle T_{r}, r\right\rangle$ on a $\Sigma$-labeled tree in which $\pi$ is labeled by $\sigma_{0}, \sigma_{1}, \ldots$, if $\left\langle T_{r}, r\right\rangle$ is consistent with a running strategy in which $\pi$ is labeled $\eta_{0}, \eta_{1}, \ldots$ and a promise in which $\pi$ is labeled $\rho_{0}, \rho_{1}, \ldots$, then $\left\langle T_{r}, r\right\rangle$ contains a path that visits the states $q_{0}, q_{1}, \ldots$.

Recall that $\Sigma^{\prime} \subseteq \Sigma \times F \times G$. We refer to a $\Sigma^{\prime}$-labeled tree as $\langle T,(V, f, g)\rangle$, where $V, f$, and $g$ are the projections of the tree on $\Sigma, F$, and $G$, respectively. We say that a running strategy $\langle T, f\rangle$ and a promise $\langle T, g\rangle$ are good for $\langle T, V\rangle$ if all the infi nite traces induced by paths in $\langle T,(V, f, g)\rangle$ satisfy the acceptance condition $\alpha$.

Consider a $\Sigma$-labeled tree $\langle T, V\rangle$, a running strategy $\langle T, f\rangle$, and a promise $\langle T, g\rangle$. We say that $g$ fulfills $f$ for $V$ if the states promised to be visited by $g$ satisfy the obligations induced by $f$ as it runs on $V$. Formally, $g$ fulfi lls $f$ for $V$ if for every node $x \in T$, and state $q$ such that $x$ is obliged to $q$ by $f, g$, and $V$, the following hold:

1. For every atom $\langle n\rangle s \in f(x)(q)$, at least $n+1$ children $x \cdot j$ of $x$ have $s \in g(x \cdot j)(q)$.
2. For every atom $[n] s \in f(x)(q)$, at least $\operatorname{deg}(x)-n$ children $x \cdot j$ of $x$ have $s \in$ $g(x \cdot j)(q)$.

Theorem 3. A GAPT $\mathcal{A}$ accepts $\langle T, V\rangle$ iff there exist a running strategy $\langle T, f\rangle$ and a promise $\langle T, g\rangle$ such that $f$ is relevant for $V, f$ and $g$ are $\operatorname{good}$ for $\langle T, V\rangle$, and $g$ fulfills $f$ for $V$.

Intuitively, if $f$ and $g$ as above exist, the $(T \times Q)$-labeled trees that are consistent with $f$ and $g$ suggest legal accepting runs of $\mathcal{A}$ on $\langle T, V\rangle$.

Annotating input trees with restrictions and local promises enables us to transform GAPT to GNPT, with an exponential blow up:

Theorem 4. Consider a GAPT $\mathcal{A}$ such that $\mathcal{A}$ runs on $\Sigma$-labeled trees. There is a GNPT $\mathcal{A}^{\prime}$ such that $\mathcal{A}^{\prime}$ runs on $\Sigma^{\prime}$-labeled trees and the following hold:

1. $\mathcal{A}^{\prime}$ accepts a tree iff $\mathcal{A}$ accepts its projection on $\Sigma$.
2. If $\mathcal{A}$ has $n$ states, index $k$, and counting bound b, then $\mathcal{A}^{\prime}$ has $2^{n(2+k \log n k)}$ states, index $n k$, and $b$-counting constraints.

Proof. Let $\mathcal{A}=\left\langle\Sigma, b, Q, \delta, q_{0}, \alpha\right\rangle$ with $\alpha=\left\{F_{1}, \ldots, F_{k}\right\}$. The automaton $\mathcal{A}^{\prime}$ is the intersection of two automata $\mathcal{A}_{1}^{\prime}$ and $\mathcal{A}_{2}^{\prime}$. The automaton $\mathcal{A}_{1}^{\prime}$ is a forall GNPT and it accepts a tree $\langle T,(V, f, g)\rangle$ iff $f$ and $g$ are good for $V$. The automaton $\mathcal{A}_{2}^{\prime}$ is a safety GNPT, and it accepts a tree $\langle T,(V, f, g)\rangle$ iff $g$ fulfi lls $f$ for $V$. Note that, since $\Sigma$ contains only triplets $\langle\sigma, \eta, \rho\rangle$ for which $\eta$ is relevant to $\sigma$, it must be that $f$ is relevant to $V$. Thus, by Theorem 3, it follows that $\mathcal{A}^{\prime}$ accepts $\langle T,(V, f, g)\rangle$ iff $\mathcal{A}$ accepts $\langle T, V\rangle$.

In order to defi ne $\mathcal{A}_{1}$, we first defi ne a nondeterministic co-parity word automaton $\mathcal{U}$ over $\Sigma^{\prime}$ such that $\mathcal{U}$ accepts a word if some trace it induces is infi nite and violates the acceptance condition $\alpha$. We defi ne $\mathcal{U}=\left\langle\Sigma, S, M, s_{0}, F^{\prime}\right\rangle$, where

- $S=(Q \times Q \times\{1, \ldots, k\}) \cup\left\{q_{a c c}\right\}$. Intuitively, a state $\left\langle q, q_{p r e v}, v\right\rangle$ indicates that the current state of the trace is $q$, that it was reached by following a step whose last transition is from the state $q_{\text {prev }}$, and the value of the step is $v$ (note that values are calculated with respect to $\alpha$ ). Thus, $q$ corresponds to states $q_{i+1}$ in traces for which $\operatorname{pos}(i+1)=\operatorname{pos}(i)+1$. The number $v$ is used for the acceptance condition. In addition, $q_{\text {prev }}$ is used for checking the obligation of the current position, given a local promise in the input word.
- For every $\left\langle q, q_{\text {prev }}, v\right\rangle \in S$ and $\langle\sigma, \eta, \rho\rangle \in \Sigma^{\prime}$, we distinguish between two cases.
- If $q \notin \rho\left(q_{\text {prev }}\right)$, then the current position is not obliged to $q$ and $M\left(\left\langle q, q_{\text {prev }}, v\right\rangle,\langle\sigma, \eta, \rho\rangle\right)=$ $\emptyset$.
- Otherwise, we again distinguish between two cases.
* If there is a rejecting $\varepsilon$-lasso of $\eta$ with $q$ and $\sigma$, then $M\left(\left\langle q, q_{\text {prev }}, v\right\rangle,\langle\sigma, \eta, \rho\rangle\right)=$ $\left\{q_{a c c}\right\}$.
* Otherwise, $\left\langle q^{\prime}, q_{p r e v}^{\prime}, v^{\prime}\right\rangle \in M\left(\left\langle q, q_{p r e v}, v\right\rangle,\langle\sigma, \eta, \rho\rangle\right)$ iff there is a step $q, \ldots, q_{p r e v}^{\prime}, q^{\prime}$ of $\eta$ with $q$ and $\sigma$ such that the value of the step is $v^{\prime}$.
In addition, $M\left(q_{a c c},\langle\sigma, \eta, \rho\rangle\right)=\left\{q_{a c c}\right\}$ for all $\langle\sigma, \eta, \rho\rangle \in \Sigma^{\prime}$. Intuitively, $\mathcal{U}$ checks whether a possible step of $\eta$ with $q$ and $\sigma$ can participate in a rejecting trace. If the current position is not obliged to the current state, no step of $\eta$ can participate in a trace, so $\mathcal{U}$ gets stuck. Otherwise, if there is a rejecting $\varepsilon$-lasso of $\eta$ with $q$ and $\sigma$, a rejecting trace is found and $\mathcal{U}$ moves to an accepting sink. Otherwise, $\mathcal{U}$ guesses other possible steps of $\eta$ with $q$ and $\sigma$, and moves to a state which remembers the last two states visited in the step (possibly $q_{\text {prev }}^{\prime}=q$ ), and the value of the step.
$-s_{0}^{\prime}=\left\langle q_{0}, q_{0}, l\right\rangle$, where $l$ is such that $q_{0} \in F_{l}$. Note that the choice of the second element is arbitrary, as the local promise at the root of the input tree is irrelevant.
- The co-parity condition is $F^{\prime}=\left\{F_{1}^{\prime}, F_{2}^{\prime}, \ldots, F_{k}^{\prime}\right\}$, where for $l \geq 2$, we have $F_{l}^{\prime}=$ $Q \times Q \times\{l\}$, and $F_{1}^{\prime}=(Q \times Q \times\{1\}) \cup\left\{q_{a c c}\right\}$. That is, acceptance is determined with respect to the values of the steps taken along the trace. Also, since $F^{\prime}$ is a co-parity condition, the accepting sink $q_{a c c}$ is in $F_{1}^{\prime}$.

In order to get $\mathcal{A}_{1}^{\prime}$, we co-determinize $\mathcal{U}$ (note that $\mathcal{U}$ does not have $\varepsilon$-transitions) and expand it to a tree automaton on $\Sigma^{\prime}$. That is, we first construct a deterministic parity word automaton $\tilde{\mathcal{U}}$ that complements $\mathcal{U}$, and then replace a transition $\tilde{M}(s, \tau)=s^{\prime}$ in $\tilde{\mathcal{U}}$ by a transition $\tilde{M}_{t}(s, \tau)=\left\{\left\langle\neg \theta_{s^{\prime}},(\leq, 0)\right\rangle\right\}$ in $\mathcal{A}_{1}^{\prime}$, where the states of $\tilde{\mathcal{U}}$ are encoded by some set $Y_{1}$ of variables and for every state $s^{\prime}$, the formula $\theta_{s^{\prime}} \in \mathcal{B}\left(Y_{1}\right)$ holds only in the subset of $Y_{1}$ that encodes $s^{\prime}$. By [Saf89,Tho97], the automaton $\tilde{\mathcal{U}}$ has $(n k)^{n k}$ states and index $n k$, thus so does $\mathcal{A}_{1}^{\prime}$. Hence $\left|Y_{1}\right|=n k \log n k$.

It is left to defi ne the safety GNPT $\mathcal{A}_{2}$. Let $Q_{\text {prev }}=\left\{q_{\text {prev }}: q \in Q\right\}$ be a copy of $Q$ in which each state is tagged with prev. The state space of $\mathcal{A}_{2}^{\prime}$ is $Q^{\prime}=2^{Q \cup Q_{p r e v}}$. Intuitively, each state $q^{\prime}$ of $\mathcal{A}_{2}^{\prime}$ corresponds to a pair $\left\langle P, P_{\text {prev }}\right\rangle \in Q \times Q$, with $P=q^{\prime} \cap Q$ and $P_{\text {prev }}$ is obtained from $q^{\prime} \cap Q_{\text {prev }}$ by removing the prev tags. The element $P$ of $q^{\prime}$ is a set of "commitments" that the current node should satisfy. The element $P_{p r e v}$ is used for remembering the state of $\mathcal{A}$ that is visited in the parent node. When $\mathcal{A}_{2}^{\prime}$ is in state $\left\langle P, P_{\text {prev }}\right\rangle$ and reads the letter $\langle\sigma, \eta, \rho\rangle$, it checks that all the commitments in $P$ are covered by the
local promise $\rho\left(P_{\text {prev }}\right)$ in the input, and it delivers, for each $q \in P$, the requirements on the children as specifi ed in $\eta(q)$.

Consider a state $\left\langle P, P_{p r e v}\right\rangle \in Q^{\prime}$ and a letter $\langle\sigma, \eta, \rho\rangle \in \Sigma^{\prime}$. For every $q \in P$, let $C_{\sigma, \eta}^{q}$ be the $b$-counting restriction in $\mathcal{C}(Q, b)$ imposed by $\eta(q)$. (If $\eta(q)$ is undefi ned, we do not care about $C_{\sigma, \eta}^{q}$, since, as we see shortly, in that case $\mathcal{A}_{2}^{\prime}$ simply gets stuck.) Thus,

$$
C_{\sigma, \eta}^{q}=\{\langle s,(>, n)\rangle:\langle n\rangle s \in \eta(q)\} \cup\{\langle\neg s,(\leq, n)\rangle:[n] s \in \eta(q)\} .
$$

Intuitively, $C_{\sigma, \eta}^{q}$ restricts the tuple of the states that visit the children of the current node, which is visited by $\left\langle P, P_{\text {prev }}\right\rangle$, so that $\eta(q)$ is satisfi ed by the first elements of the states. In addition, the second element of the states in the tuple should be the encoding of $P$ tagged with prev. This is done by the counting constraint $\left\{\left\langle\neg \theta_{P}^{\text {prev }},(\leq, 0)\right\rangle\right\}$, where $\theta_{P}^{\text {prev }} \in$ $\mathcal{B}\left(Q_{\text {prev }}\right)$ is such that the only set that satisfi es $\theta_{P}^{\text {prev }}$ is the encoding of $P$ tagged with prev. Finally, for every $P \in 2^{Q}$, let $C_{\sigma, \eta}^{P}=\left(\oplus_{q \in P} C_{\sigma, \eta}^{q}\right) \cup\left\{\left\langle\neg \theta_{P}^{\text {prev }},(\leq, 0)\right\rangle\right\}$.

Then, $\mathcal{A}_{2}^{\prime}=\left\langle\Sigma^{\prime}, Q^{\prime}, \delta^{\prime},\left\{q_{0}, q_{0}\right\}\right\rangle$, where for every $\left\langle P, P_{\text {prev }}\right\rangle \in Q^{\prime}$ and $\langle\sigma, \eta, \rho\rangle \in \Sigma^{\prime}$, we have
$\delta^{\prime}\left(\left\langle P, P_{\text {prev }}\right\rangle,\langle\sigma, \eta, \rho\rangle\right)=\left[\begin{array}{ll}\emptyset & \text { if } \rho\left(P_{\text {prev }}\right) \nsubseteq P \text { or there is } q \in P \text { for which } \eta(q) \text { is undefi ned, } \\ C_{\sigma, \eta}^{P} & \text { otherwise. }\end{array}\right.$
Note that $Q^{\prime}$ is defi ned with respect to the $2 n$ variables $Q \cup Q_{p r e v}$. Also, all the formulas $\theta$ that are paired to constraints in $C_{\sigma, \eta}^{P}$ are either $s$ or $\neg s$, for $s \in Q$, or $\neg \theta_{P}^{p r e v}$. Hence, the counting constraints in $\mathcal{A}_{2}^{\prime}$ are in $\mathcal{C}\left(Q \cup Q_{\text {prev }}, b\right)$.

Now, by Lemma 2, we can defi ne the the intersection $\mathcal{A}$ of $\mathcal{A}_{1}^{\prime}$ and $\mathcal{A}_{2}^{\prime}$ as a GNPT with $2^{n(2+k \log n k)}$ states, index $n k$, and $b$-counting constraints.

### 4.2 The nonemptiness problem for GNPT

In a nondeterministic parity tree automaton $\mathcal{U}=\left\langle\Sigma, Q, M, q_{0}, \alpha\right\rangle$, the transition function $M: Q \times \Sigma \rightarrow 2^{Q^{*}}$ maps a state and a letter to a set of possible tuples for the children states. Thus, a run of nondeterministic tree automaton on a tree $\langle T, V\rangle$ is a $Q$-labeled tree $\langle T, r\rangle$ in which $r(\varepsilon)=q_{0}$ and for all $x \in T$, the tuple $\langle r(x \cdot 1), r(x \cdot 2), \ldots, r(x \cdot \operatorname{deg}(x))\rangle \in$ $M(r(x), V(x))$. The nonemptiness test for parity tree automata then uses the local test is_mother : $2^{Q} \times Q \rightarrow\{$ true, false $\}$ that given a set $S \subseteq Q$ and a state $q$, returns true iff there is a tuple $t \in S^{*}$ and $\sigma \in \Sigma$ such that $t \in M(q, \sigma)$. It is easy to see how the $i s \_m o t h e r ~ t e s t ~ i s ~ u s e d ~ i n ~ a ~ b o t t o m-u p ~ n o n e m p t i n e s s ~ a l g o r i t h m ~ f o r ~ a u t o m a t a ~ o n ~ f i ~ n i t e ~ t r e e s, ~$ where in order to find the set $S$ of states from which the automaton accepts some tree, one starts with the set $S_{0}$ of accepting states then defin ne $S_{i+1}$ as the set of states $q$ such that either $q$ is in $S_{i}$ or $i s \_$mother $(t, q)=$ true. In parity automata, the algorithm is more complicated, as one has to also keep track of the acceptance condition, but the same local test is used. Several nonemptiness algorithms for nondeterministic parity tree automata are known. In particular, the algorithms in [EJS93,KV98] use $O\left(n^{k}\right)$ calls to is_mother, where $n$ is the size of $Q$ and $k$ is the index of the automaton.

Recall that in GNPT, a run $\langle T, r\rangle$ should satisfy $r(\varepsilon)=q_{0}$ and for all $x \in T$, the tuple $\langle r(x \cdot 1), r(x \cdot 2), \ldots, r(x \cdot \operatorname{deg}(x))\rangle$ satisfi es $\delta(r(x), V(x))$, which is a $b$-counting constraint. Thus, the nonemptiness test is similar, only that the local test is_mother : $2^{Q} \times$ $Q \rightarrow\{$ true, false $\}$ now returns true for a set $S \subseteq Q$ and a state $q$, iff there is $t \in S^{*}$ and $\sigma \in \Sigma$ such that $t$ satisfi es $\delta(q, \sigma)$. As with nondeterministic automata, the nonemptiness algorithm can do $O\left(n^{k}\right)$ calls to is_mother. Unlike the case for nondeterministic automata,
however, here there is no simple transition function to consult when we perform the local test. In addition, we should take into an account the fact that the GNPT whose emptiness we check have larger alphabets than the GAPT we have started with.

Consider a GAPT $\mathcal{A}=\left\langle\Sigma, b, Q, \delta, q_{0}, \alpha\right\rangle$ with $n$ states, index $k$, and counting bound $b$. Let us analyse carefully the complexity of the local is_mother test in the GNPT $\mathcal{A}^{\prime}$ we constructed from $\mathcal{A}$ in Theorem 4. First, $\mathcal{A}^{\prime}$ has counting constraints in $\mathcal{C}\left(Y^{\prime}, b\right)$, for $Y^{\prime}$ of size $n(2+k \log n k)$. Hence, by Lemma 1, given $S$, the check whether there is a tuple $t \in S^{*}$ such that $t$ satisfi es $\delta\left(q, \sigma^{\prime}\right)$, for a particular $\sigma^{\prime} \in \Sigma^{\prime}$, can be done in time $\left.O(2 b+2)^{n(2+k \log n k)}\right)$. Now, $\Sigma^{\prime} \subseteq \Sigma \times F \times G$, where $F$ is the set of restrictions for $\delta$ and $G$ is the set of all local promises. Let $|\Sigma|=l$. Recall that a restriction relevant to a letter $\sigma \in \Sigma$ maps a state $q \in Q$ to a subset of $D_{b} \times Q$ that satisfi es $\delta(q, \sigma)$. We can restrict our attention to restrictions in which each state is paired with at most one element of $\langle\langle b\rangle\rangle$, one element of $[\langle b\rangle]$, and $\varepsilon$. Thus, $|F|$ is bounded by $(2 b+4)^{n^{2}}$ and $|G|$ is bounded by $2^{n^{2}}$. It follows that $\left|\Sigma^{\prime}\right| \leq l(2 b+4)^{n^{2}} 2^{n^{2}}$, thus is_mother can be checked in time $l(b+2)^{O(n(n+2+k \log n k)}$. Since, as in [EJS93,KV98], the nonemptiness problem can be solved by $O\left(n^{k}\right)$ applications of is_mother, we have the following.

Theorem 5. The nonemptiness problemfor $\mathcal{A}^{\prime}$ can be solved in time $n^{k} l(b+2)^{O(n(n+2+k \log n k))}$.
For a graded $\mu$-calculus formula $\psi$, we get, by Theorem 2 , a GAPT $\mathcal{A}$ with $n$ and $k$ bounded by $|\psi|$, and the same counting bound $b$ as $\psi$. While $b$ and $l$ may be exponential in $|\psi|$, only $n$ and $k$ appear in the exponents in the expression in Theorem 5. This implies the upper bound in the theorem below. The lower bound is due to the fact that the $\mu$-calculus is known to be EXPTIME-hard [FL79].

Corollary 1. The satisfiability problem for graded $\mu$-calculus is EXPTIME-complete even if the numbers in the graded modalities are coded in binary.

Note that the space and time bounds in Lemma 1 stay valid for counting constraints that involve richer bounds than $(>, n)$ and $(\leq, n)$. For example, we can handle bounds of the form $\left(>, \frac{1}{2}\right)$ or $\left(\leq, \frac{1}{2}\right)$, bounding the fraction of elements in the tuple that satisfy a predicate (of course, this is applicable only to structures where all points have only fi nitely many successors). In general, Lemma 1 can handle arbitrary polynomial predicates $\alpha \subseteq \mathbb{N}^{2}$, where a tuple $t \in\left(2^{Y}\right)^{m}$ satisfi es such a constraint $\langle\theta, \alpha\rangle$ if $\alpha($ weight $(\operatorname{sat}(\theta), t), m)$ holds. By defi ning the corresponding types of alternating automata, we can thus handle $\mu$-calculus formulas with richer types of modalities.

## A Tree Model Property

In this section we show that the graded $\mu$-calculus has the tree model property. Thus, if a formula $\varphi$ is satisfi able, it is also satisfi able in a tree. Moreover, the number of atleast formulas in $\varphi$ and its counting bound induce a suffi cient branching degree for the tree.

We fi rst need some defi nitions. The closure of a sentence $\psi$, denoted $\mathbf{c l}(\psi)$, is the smallest set of sentences that satisfi es the following:

- $\psi \in \operatorname{cl}(\psi)$,
- if $\varphi_{1} \wedge \varphi_{2} \in \operatorname{cl}(\psi)$ or $\varphi_{1} \vee \varphi_{2} \in \operatorname{cl}(\psi)$, then $\left\{\varphi_{1}, \varphi_{2}\right\} \subseteq \operatorname{cl}(\psi)$,
- if $\langle n\rangle \varphi \in \operatorname{cl}(\psi)$ or $[n] \varphi \in \mathrm{cl}(\psi)$, then $\varphi \in \mathrm{cl}(\psi)$, and
- if $\lambda x . \varphi(x) \in \mathrm{cl}(\psi)$, then $\varphi(\lambda x \cdot \varphi(x)) \in \mathrm{cl}(\psi)$.

An atom of $\psi$ is a maximal consistent set $A$ of formulas in $\mathrm{cl}(\psi)$. Formally, $A$ satisfi es the following properties:

- if $p \in \mathrm{AP}$ occurs in $\psi$, then $p \in A$ iff $\neg p \notin A$,
- if $\varphi_{1} \wedge \varphi_{2} \in \operatorname{cl}(\psi)$, then $\varphi_{1} \wedge \varphi_{2} \in A$ iff $\left\{\varphi_{1}, \varphi_{2}\right\} \subseteq A$,
- if $\varphi_{1} \vee \varphi_{2} \in \mathrm{cl}(\psi)$, then $\varphi_{1} \vee \varphi_{2} \in A$ iff $\left\{\varphi_{1}, \varphi_{2}\right\} \cap A \neq \emptyset$, and
- if $\lambda x \cdot \varphi(x) \in \mathrm{cl}(\psi)$, then $\lambda x \cdot \varphi(x) \in A$ iff $\varphi(\lambda x \cdot \varphi(x)) \in A$.

The set of atoms of $\psi$ is denoted at $(\psi)$.
A pre-model $\langle K, \pi\rangle$ for a sentence $\psi$ consists of a Kripke structure $K=\langle\mathrm{AP}, W, R, L\rangle$ and a mapping $\pi: W \rightarrow$ at $(\psi)$ that satisfi es the following properties:

- there is $u_{0} \in W$ with $\psi \in \pi\left(u_{0}\right)$,
- for $p \in \mathrm{AP}$, if $p \in \pi(u)$ then $u \in L(p)$, and if $\neg p \in \pi(u)$ then $u \notin L(p)$,
- if $\langle n\rangle \varphi \in \pi(u)$, then there is $V \subseteq \operatorname{succ}_{R}(u)$ such that $|V|>n$ and $\varphi \in \pi(v)$ for all $v \in V$, and
- if $[n] \varphi \in \pi(u)$, then there is $V \subseteq \operatorname{succ}_{R}(u)$ such that $|V| \leq n$ and $\varphi \in \pi(v)$ for all $v \in \operatorname{succ}_{R}(u) \backslash V$.

A choice function for a pre-model $\langle K, \pi\rangle$ of $\psi$ is a partial function $\mathrm{ch}: W \times \operatorname{cl}(\psi) \rightarrow$ $\mathrm{cl}(\psi) \cup 2^{W}$ such that for all $u \in W$, the following hold.

- If $\varphi_{1} \vee \varphi_{2} \in \pi(u)$, then $\operatorname{ch}\left(u, \varphi_{1} \vee \varphi_{2}\right) \in\left\{\varphi_{1}, \varphi_{2}\right\} \cap \pi(u)$.
- If $\langle n\rangle \varphi \in \pi(u)$, then $\operatorname{ch}(u,\langle n\rangle \varphi)=V \subseteq \operatorname{succ}_{R}(u)$ such that $|V|>n$ and $\varphi \in \pi(v)$ for all $v \in V$.
- if $[n] \varphi \in \pi(u)$, then $\operatorname{ch}(u,[n] \varphi)=V \subseteq \operatorname{succ}_{R}(u)$ such that $|V| \leq n$ and $\varphi \in \pi(v)$ for all $v \in \operatorname{succ}_{R}(u) \backslash V$.

An adorned pre-model $\langle K, \pi, \mathrm{ch}\rangle$ consists of a pre-model $\langle K, \pi\rangle$ together with a choice function ch. For an adorned pre-model $\langle\langle\mathrm{AP}, W, R, L\rangle, \pi, \mathrm{ch}\rangle$ of $\psi$, the derivation relation $\leadsto \subseteq(W \times \mathrm{cl}(\psi)) \times(W \times \mathrm{cl}(\psi))$ is defi ned as follows:

- if $\varphi_{1} \vee \varphi_{2} \in \pi(u)$, then $\left(u, \varphi_{1} \vee \varphi_{2}\right) \leadsto\left(u, \operatorname{ch}\left(\varphi_{1} \vee \varphi_{2}\right)\right)$
- if $\varphi_{1} \wedge \varphi_{2} \in \pi(u)$, then $\left(u, \varphi_{1} \wedge \varphi_{2}\right) \leadsto\left(u, \varphi_{1}\right)$ and $\left(u, \varphi_{1} \wedge \varphi_{2}\right) \leadsto\left(u, \varphi_{2}\right)$.
- if $\langle n\rangle \varphi \in \pi(u)$, then $(u,\langle n\rangle \varphi) \leadsto(v, \varphi)$ for each $v \in \operatorname{ch}(u,\langle n\rangle \varphi)$,
- if $[n] \varphi \in \pi(u)$, then $(u,[n] \varphi) \leadsto(v, \varphi)$ for each with $v \in \operatorname{succ}_{R}(u) \backslash \operatorname{ch}([n] \varphi)$,
- if $\lambda x \cdot \varphi(x) \in \pi(u)$, then $(u, \lambda x \cdot \varphi(x)) \leadsto(u, \varphi(\lambda x \cdot \varphi(x)))$

Intuitively, the derivation relation $\leadsto$ is such that in order to derive the satisfaction of $\varphi$ in $u$ as suggested by ch, one needs to satisfy $\varphi^{\prime}$ in $u^{\prime}$, for all $\varphi^{\prime}$ and $u^{\prime}$ with $(u, \varphi) \sim\left(u^{\prime}, \varphi^{\prime}\right)$. For a least-fi xpoint sentence, one should avoid a cyclic dependency in the derivation chain. Formally, we say that a least-fi xpoint sentence $\mu x . \varphi(x)$ is regenerated from point $u$ to point $v$ in an adorned pre-model $\langle K, \pi$, ch $\rangle$ if there is a sequence $\left(\rho_{1}, u_{1}\right), \ldots,\left(\rho_{k}, u_{k}\right) \in$ $(\mathrm{cl}(\psi) \times W)^{*}$ with $k \geq 2$ such that $\rho_{1}=\rho_{k}=\mu x \cdot \varphi(x), u=u_{1}, v=u_{k}$, the formula $\mu x . \varphi(x)$ is a sub-sentence of each $\rho_{i}$ in the sequence, and for all $1 \leq i<k$, we have $\left(\rho_{i}, u_{i}\right) \leadsto\left(\rho_{i+1}, u_{i+1}\right)$. We then say that $\langle K, \pi, \mathrm{ch}\rangle$ is well-founded if there is no least fi xpoint sentence $\mu x . \varphi(x) \in \mathrm{cl}(\psi)$ and an infi nite sequence $\notin, u_{1}, \ldots$ such that, for each $i \geq 0, \mu x . \varphi(x)$ is regenerated from $u_{i}$ to $u_{i+1}$.

Lemma 3. A sentence $\psi$ has a model $K$ iff $\psi$ has a well-founded adorned pre-model $\langle K, \pi, \mathrm{ch}\rangle$.

Proof (sketch): Assume first that $\psi$ has a well-founded adorned pre-model $\langle K, \pi, \mathrm{ch}\rangle$. The proof that $K$ is then a model of $\psi$ is very similar to the analogous claim for $\mu$-calculus formulas [SE89]. For the other direction, we should show that given a model $K$ of $\psi$, we can tag each state of $K$ with an atom and a choice function and get a well-founded adorned pre-model. This direction is harder, as it is not clear that the same choice can be made in different visits to the same state of $K$. In [EJ91] (see also [Tho97]), a memoryless winning strategy is defi ned for parity games. The strategy being memoryless means that the same choice is made by the strategy in different visits to the same position of the game. Since $\mu$-calculus formulas correspond to parity games, this implies the correctness of the lemma for a $\mu$-calculus formula $\psi$. As we now show, graded $\mu$-calculus formulas also correspond to parity games. A position of the game is a pair $\langle U, \varphi\rangle$ where $U \subseteq W$ is a set of points and $\varphi$ is a formula. Essentially, the game is played between player 1 , who tries to show that $\varphi$ is satisfi ed in all the points in $U$, and player 2, who tries to show the opposite. Assume that the current position of the game is $\langle U, \varphi\rangle$. When the set $U$ is not a singleton, player 2 chooses $u \in U$ and the game moves to position $\langle u, \varphi\rangle$. When $U=\{u\}$ is a singleton, the game proceeds as follows. If $\varphi=\varphi_{1} \wedge \varphi_{2}$, then player 2 chooses $\varphi_{i}$ and the game moves to position $\left\langle u, \varphi_{i}\right\rangle$. On the other hand, when $\varphi=\varphi_{1} \vee \varphi_{2}$, player 1 chooses the $\varphi_{i}$ to move to. Formulas of the form $\langle n\rangle \varphi^{\prime}$ and $[n] \varphi^{\prime}$ also involve a disjunction, and player 1 proceeds by picking the set of successors that should satisfy $\varphi^{\prime}$, thus the new position is $\left\langle U^{\prime}, \varphi^{\prime}\right\rangle$, where the size of $U^{\prime} \subseteq \operatorname{succ}_{R}(u)$ is $n+1$ or $\operatorname{deg}(u)-n$, respectively. Recall that then, player 2 chooses the point in $U^{\prime}$ to continue with. Finally, when $\varphi$ is of the form $\lambda x \cdot \varphi^{\prime}(x)$, the new position is $\left\langle u, \varphi^{\prime}\left(\lambda x \cdot \varphi^{\prime}(x)\right)\right\rangle$. Note that in parity games that correspond to $\mu$-calculus formulas (equivalently, in the game described above with $n=0$ ), the set $U$ is always a singleton. The parity winning condition is similar to the one for $\mu$-calculus. Now, as in [SE89], the a memoryless strategy in the game induces the required choice function and implies the existence of a well-founded adorned pre-model.

Theorem 6. Consider a sentence $\psi$ such that $\psi$ has $l$ atleast subsentences, each counting to at most $b$. If $\psi$ is satisfiable, then $\psi$ is satisfied in a tree with branching degree bounded byl $l(b+1)$.

Proof. Assume that $\psi$ be satisfi able. By Lemma 3, $\psi$ has a well-founded adorned premodel $\langle K, \pi, \mathrm{ch}\rangle$. Let $K=\langle\mathrm{AP}, W, R, L\rangle$ and let $w_{0} \in W$ be such that $w_{0} \in \psi^{K}$. Also, let $\left\langle n_{1}\right\rangle \varphi_{1}, \ldots,\left\langle n_{l}\right\rangle \varphi_{l}$ be all the atleast formulas in $\operatorname{cl}(\psi)$. Recall that $b=\max \left\{n_{i} \mid 1 \leq\right.$ $i \leq l\}$. We embody $\langle K, \pi, c h\rangle$ in a tree with branching degree bounded by $l(b+1)$. For that, we defi ne a partial mapping $\tau:\{1, \ldots, l(b+1)\}^{*} \rightarrow W$ inductively, together with an adorned pre-model $\left\langle K^{\prime}, \pi^{\prime}, \mathrm{ch}^{\prime}\right\rangle$, where $K^{\prime}=\left\langle\mathrm{AP}, W^{\prime}, R^{\prime}, L^{\prime}\right\rangle$ is such that $W^{\prime}$ is the subset of $\{1, \ldots, l(b+1)\}^{*}$ for which $\tau$ is defi ned. The functions $L^{\prime}$ and $\pi^{\prime}$ are directly induced by $L$ and $\pi$. Formally, for a point $x \in W^{\prime}$, we defi ne $\pi^{\prime}(x)=\pi(\tau(x))$, and for an atomic proposition $p \in \mathrm{AP}$, we defi ne $x \in L^{\prime}(p)$ iff $\tau(x) \in L(p)$. The choice function $\mathrm{ch}^{\prime}$ for disjunctions is also directly induced by ch. Formally, $\operatorname{ch}^{\prime}\left(x, \varphi_{1} \vee \varphi_{2}\right)=\operatorname{ch}\left(\tau(x), \varphi_{1} \vee\right.$ $\varphi_{2}$ ).

It is left to defi ne $R$ and the choice function $\mathrm{ch}^{\prime}$ for atleast and allbut subsentences. This is done inductively, together with the defi nition of $\tau$. The induction proceeds on the length of the nodes $x \in\{1, \ldots, l(b+1)\}^{*}$. For the induction base, we set $\tau(\varepsilon)=w_{0}$. Let
$i \geq 0$ be such that $\tau(x)$ is already defi ned for nodes in $x \in\{1, \ldots, l(b+1)\}^{i}$. Then, for all $x \in\{1, \ldots, l(b+1)\}^{i}$ for which $\tau(x)$ is defi ned and for all $1 \leq j \leq l$, we do the following.

- If $\left\langle n_{j}\right\rangle \varphi_{j} \in \pi^{\prime}(x)$, then, since $\langle K, \pi$, ch $\rangle$ is a pre-model and $\pi^{\prime}(x)=\pi(\tau(x))$, we have that $\operatorname{ch}\left(\tau(x),\left\langle n_{j}\right\rangle \varphi_{j}\right)=\left\{v_{1}, \ldots, v_{n_{j}+1}\right\} \subseteq \operatorname{succ}_{R}(\tau(x))$ is such that for all $1 \leq r \leq n_{j}+1$, we have $\varphi_{j} \in \pi\left(v_{r}\right)$. For all $1 \leq r \leq n_{j}+1$, we do the following.
(i) If there is some $j^{\prime}$ such that $\tau\left(x \cdot j^{\prime}\right)=v_{r}$, we add $x \cdot j^{\prime}$ to the set $\mathrm{ch}^{\prime}\left(x,\left\langle n_{j}\right\rangle \varphi_{j}\right)$.
(ii) Otherwise, we set $\tau(x \cdot(j-1) l+r)=v_{r}$, add $\langle x, x((j-1) l+r)\rangle$ to $R^{\prime}$, and add $x \cdot((j-1) l+r)$ to $\mathrm{ch}^{\prime}\left(x,\left\langle n_{j}\right\rangle \varphi_{j}\right)$.
- for each $x$ with $\tau(x) \in W$ and $[n] \varphi \in \pi^{\prime}(x)$, we set $\operatorname{ch}^{\prime}(x,[n] \varphi)=\{x \cdot j \mid \tau(x \cdot j) \in$ $\operatorname{ch}(\tau(x),[n] \varphi)\}$.

Since $\langle K, \pi, \mathrm{ch}\rangle$ is an adorned pre-model, so is $\left\langle K^{\prime}, \pi^{\prime}, \mathrm{ch}^{\prime}\right\rangle$. Moreover, if a sentence $\mu x . \varphi(x)$ is regenerated from $x$ to $y$ in $\left(K^{\prime}, \pi^{\prime}, \mathrm{ch}^{\prime}\right)$, then $\mu x . \varphi(x)$ is also regenerated from $\tau(x)$ to $\tau(y)$ in $\langle K, \pi, \mathrm{ch}\rangle$. Thus, since $\langle K, \pi, \mathrm{ch}\rangle$ is well-founded, so is $\left\langle K^{\prime}, \pi^{\prime}, \mathrm{ch}^{\prime}\right\rangle$. Finally, since all the transitions in $R^{\prime}$ are from a node in the tree $\{1, \ldots, l \cdot(b+1)\}^{*}$ to its children in the tree, then $K^{\prime}$ is the tree we seek, and $\psi$ is satisfi ed in its root $\varepsilon$.

[^0]:    ${ }^{1}$ A graded $\mu$-calculus sentence is guarded if for all $y \in \operatorname{Var}$, all the occurrences of $y$ that are in a scope of a fixpoint modality $\lambda$ are also in a scope of a graded modality that is itself in the scope of $\lambda$. Thus, a $\mu$-calculus sentence is guarded if for all $y \in \operatorname{Var}$, all the occurrences of $y$ are in the scope of a graded modality. For example, the formula $\mu y \cdot(p \vee\langle 0\rangle y)$ is guarded and the formula $\langle 0\rangle \mu y .(p \vee y)$ is not guarded. Given a graded $\mu$-calculus formula, we can construct, in linear time, an equivalent guarded formula (see [BB87,KVW00] for a proof for $\mu$-calculus, which is easily extendible to graded $\mu$-calculus). Accordingly, we assume that all formulas are guarded. This is essential for the correctness of the construction in the proof.

[^1]:    ${ }^{2}$ To keep the $\oplus$ operator efficient, we do not care for redundancies and contradictions that originate from the relation between the formulas in the constraints. For example, a minimized $C$ may contain both $\left\langle\theta_{1},(>, n)\right\rangle$ and $\left\langle\theta_{2},(>, n)\right\rangle$ for $\theta_{1}$ that implies $\theta_{2}$, and it may contain both $\langle\theta,(>, n)\rangle$ and $\langle\theta,(\leq, n)\rangle$
